## Question 1

(a)

Explain how a substitution cipher works.

#### Answer (a)

A **Substitution cipher** is done by permuting (scrambling) the letters of the alphabet. For example: replacing the letter "a"  $\rightarrow$  "K". The key to a substitution cipher is a table of each permutation.

(b)

What does it mean for a substitution cipher to be

- (i) monoalphabetic?
- (ii) polyalphabetic?

#### Answer (b)

(i)

In a monoal phabetic substitution cipher, the letters are always encrypted the same.

For example: "a" will always be permuted the same, no matter the position in the plaintext.

(ii)

In a polyalphabetic substitution cipher, the latter may be encrypted differently depending on it's position in the plaintext.

For example: In a Vigenère cipher with a key length of 3, the letter "a" will be permuted differently depending on if it's in position 0,1 or 2 in the plaintext cycle. Like "a<sub>0</sub>"  $\rightarrow$  "K", "a<sub>1</sub>"  $\rightarrow$  "D" and "a<sub>2</sub>"  $\rightarrow$  "Q"

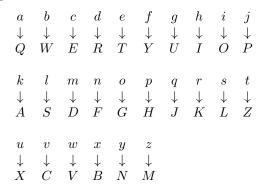

(c)

Give a non-trivial example of a monoalphabetic substitution cipher and use it to encrypt the plaintext

Teach thy necessity to reason thus There is no virtue like necessity

### Answer (c)

We first need to define a key, which looks like a table of sorts. Using this key:

our plaintext

Teach thy necessity to reason thus

There is no virtue like necessity

is encoded as:

ZTQEI ZIN FTETLLOZN ZG KTQLGF ZIXL ZITKT OL FG COKZXT SOAT FTETLLOZN

(d)

Explain how to break a monoalphabetic substitution cipher.

#### Answer (d)

By looking at the *letter frequencies* in the ciphertext, we can make guesses on what common letters they map to. By replacing the letters of digrams and trigrams in the ciphertext, to letters that's common in the English alphabet, we may start to see English words begin to form.

# Question 4

(a)

Define Euler's  $\Phi$ -function.

## Answer (a)

Euler's  $\Phi$  function on the natural numbers  $n \geq 2$  given by:

$$\Phi(n) = \#$$
 congruence classes  $[a] \in \mathbb{Z}_n$  such that  $\gcd(a, n = 1)$ 

Counts the number of invertible elements of  $Z_n$ .

(b)

Compute  $\Phi(17)$ ,  $\Phi(289)$  and  $\Phi(221)$ .

#### Answer (b)

To compute  $\Phi(n)$ , we first need to prime factorize n, and then use the following formula:

$$\Phi(n) = p_1^{a_1 - 1}(p_1 - 1)p_2^{a_2 - 1}(p_2 - 1)...p_r^{a_r - 1}(p_r - 1)$$

Where  $n = p_1^{a_1} p_2^{a_2} ... p_r^{a_r}$  and  $p_1, p_2, ..., p_r$  are distinct primes and  $a_1, a_2, ..., a_r > 0$ .

17 is already prime so we can calculate  $\Phi(17)$  as:

$$\Phi(17) = 17^{1-1}(17-1) = 16$$

289 need to be factorized before we can calculate  $\Phi$ .

$$289 = 17^2$$

$$\Phi(289) = 17^{2-1}(17-1) = 17 * 16 = 272$$

And the same thing for 221:

$$221 = 13 + 17$$

$$\Phi(221) = 13^{1-1}(13-1) + 17^{1-1}(17-1) = 12 * 16 = 192$$

## Question 5

### Answer 5

## Question 6

(a)

Explain what Friedman's Index of Coincidence measures and compute it for the ciphertext below, hence explain how you can see that the cipher used to encrypt it was not monoalphabetic.

#### Answer (a)

The  $Index\ of\ Coincidence\ ({\it IOC})\ I,$  measures the likelihood of picking 2 identical letters, from a text.

We can calculate the IOC I, by using the counted letters, given in the assignment. Where the letters: a,b,c...,z are represented as  $n_0, n_1, ..., n_{25}$ , and n is the total number of letters.

$$I = \frac{\sum_{0}^{25} n_i (n_i - 1)}{n(n - 1)}$$

$$= \frac{26(26 - 1) + 20(20 - 1) + \dots + 25(25 - 1)}{444 * 443}$$

$$= \frac{8638}{196692}$$

$$\approx 0.44$$

(b)

Actually the ciphertext has been encrypted by using a Vigenère cipher with keylength 5. Explain how the  $\chi^2$ -test for goodness of fit can be used to guess that the first letter of the keyword is  $\mathbf{f}$ . Include in your explanation full calculations to show that a guess of  $\mathbf{f}$  for first letter of the key is a better guess than the letter  $\mathbf{z}$ .

#### Answer (b)

The  $\chi^2$ -test can be used to determine the best shift. This is determined calculating  $\chi^2(\text{shift }n)$  for each shift, where the lowest value (deviation) is the best shift amount.

We begin by extracting the first letter of each column in the cipher text. This gives us the cipher text: KYXYZMJGYHMFNYNXTYXFDSQJMTPJYXFQYTF-SJNIMJJJWNYLWRNFXHXMQJNAFYMMFZJYXPJXNMMJJMINJXTXJKWHYI

We want to calculate  $\chi$  when "K" is shifted to an "f". We get "f" by shifting "K"  $\to$  "f", which gives us "a"  $\to$  "f" (shift 5).

And when we want to calculate  $\chi$  when "K" is shifted to an "z". We get "z" by shifting "K"  $\rightarrow$  "z", which gives us "a"  $\rightarrow$  "l" (shift 11).

 $\chi^2$  is calculated with the following formula

$$\chi^2 = \sum \frac{(a_i - e_i)^2}{e_i}$$

where  $a_i$  is the number of letters: a,b,c,...,z. And  $e_i$  is the expected frequency of the letter in the English alphabet (Pia's Block 1 notes, P.56).

Letter	Expected freq. $e_i$	Observed frequency $a_i$	Shift 5	Shift 11
A	5.30	1	1	7
B	0.89	0	10	1
C	1.44	0	8	3
D	2.98	1	0	3
E	8.20	0	2	14
F	1.21	7	3	2
G	1.53	1	1	1
H	4.45	3	2	10
I	4.53	3	4	8
J	0.09	14	0	0
K	0.70	2	0	2
L	2.84	1	3	3
M	1.27	10	10	1
N	4.24	8	11	2
O	4.90	0	2	4
P	0.91	2	1	0
Q	0.12	3	0	0
R	3.26	1	0	3
S	3.93	2	1	10
T	6.45	4	0	11
U	2.09	0	7	2
V	0.51	0	1	1
W	1.62	3	3	0
X	0.08	10	3	0
Y	1.37	11	14	1
Z	0.05	2	2	0

$$\chi^{2}(\text{shift 5}) = \sum \frac{(a_{i} - e_{i})^{2}}{e_{i}}$$

$$= \frac{(7 - 5.3)^{2}}{5.3} + \frac{(7 - 5.3)^{2}}{5.3} + \dots + \frac{(0 - 0.05)^{2}}{0.05}$$

$$\approx 31.51$$

$$\chi^{2}(\text{shift }11) = \sum \frac{(a_{i} - e_{i})^{2}}{e_{i}}$$

$$= \frac{(1 - 5.3)^{2}}{5.3} + \frac{(10 - 5.3)^{2}}{5.3} + \dots + \frac{(2 - 0.05)^{2}}{0.05}$$

$$\approx 536.11$$

This means that  $\chi^2(\text{shift 5})$  is the preferred shift amount for column 1, as it's lower than the value of  $\chi^2(\text{shift 11})$ .

(c)

Decrypt the first line of the ciphertext below, given that it has been encrypted by using a Vigenère cipher with the keyword **fishy**.

## KQJZR YPWMG XPEBQ YJWJY ZOZAR MILPQ JIKFY GITFG YPAUI HWMSB MINLA FCYOR

#### Answer (c)

Using the formula we can get the ciphertext  $y_i$ :

$$y_i = (x_i + k_{iMODn})MOD26$$

In this case, we are looking for the plaintext letters  $x_i$ .

The key: **fishy**, corresponds to the sequence (5,8,18,7,24) as  $y_i$ .

If we want to decrypt the cipher text "KQJZR", which in numeric corresponds to "10,16,9,25,17", we start by using  $y_0 = 10$  to decrypt K:

$$10 = (x_0 + 5_{0MOD5})MOD26$$
  

$$10 = (x_0 + 5_0)MOD26$$
  

$$5 = x_0MOD26$$
  

$$x_0 = 5$$

So the first letter "K"  $\rightarrow$  "f". Using this formula for the remaining 4 ciphertext letters, we get "KQJZR"  $\rightarrow$  "first".
